The Diophantine Frobenius problem

Let a_1, \ldots, a_n be positive integers with $a_i \ge 2$ and $(a_1, \ldots, a_n) = 1$. The following naive questions is known as "**Diophantine Frobenius problem**" (or "**Coin exchange problem**"): Determine the largest number which is not of the form

 $a_1x_1+\cdots+a_nx_n$

where the coefficients x_i are non-negative integers. This number is denoted by $g(a_1, \ldots, a_n)$ and is called the **Frobenius number**.

The Diophantine Frobenius problem

Example

Let a = 3, b = 5. Then g(a, b) = ?

< ロ > < 同 > < 回 > < 回 >

The Diophantine Frobenius problem

Example

Let a = 3, b = 5. Then g(a, b) = 7:

$$7\neq 3x+5y \qquad (x,y\geq 0),$$

but for every m > 7 there are some $x, y \ge 0$ such that m = 3x + 5y.

• • • • • • • • • • • • •

The Diophantine Frobenius problem

Example

Let a = 3, b = 5. Then g(a, b) = 7:

$$7 \neq 3x + 5y$$
 $(x, y \ge 0),$

but for every m > 7 there are some $x, y \ge 0$ such that m = 3x + 5y.

It is known that

$$g(a,b)=ab-a-a.$$

The challenge is to find $g(a_1, \ldots, a_n)$ when $n \ge 3$.

The Diophantine Frobenius problem

Example

Let a = 3, b = 5. Then g(a, b) = 7:

$$7\neq 3x+5y \qquad (x,y\geq 0),$$

but for every m > 7 there are some $x, y \ge 0$ such that m = 3x + 5y.

It is known that

$$g(a,b)=ab-a-a.$$

The challenge is to find $g(a_1, \ldots, a_n)$ when $n \ge 3$.

Example

g(3, 5, 7) = 4:

$$4 \neq 3x + 5y + 7z$$
 (*x*, *y*, *z* \geq 0).

positive Frobenius number

We shall consider

$$f(a,b,c) = g(a,b,c) + a + b + c,$$

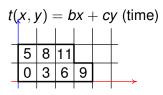

the **positive Frobenius number** of *a*, *b*, *c*, defined to be the largest integer not representable as a **positive** linear combination of *a*, *b*, *c*

$$ax + by + cz, \qquad x, y, z \ge 1.$$

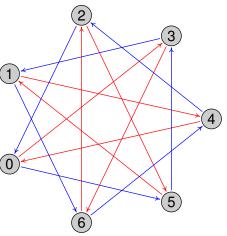

Positive Frobenius numbers are better because of Johnson's formula: for $d \mid a, d \mid b$

$$f(a,b,c) = d \cdot f\left(\frac{a}{d},\frac{b}{d},c\right).$$

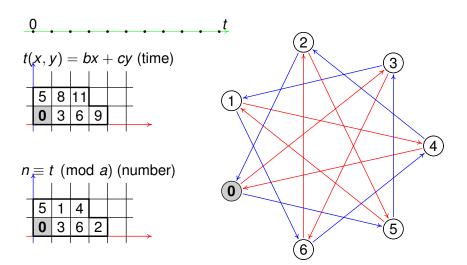

length(\uparrow)= 3, length(\uparrow)= 5

 $n \equiv t \pmod{a} \pmod{a}$ (number) 5 1 4 0 3 6 2

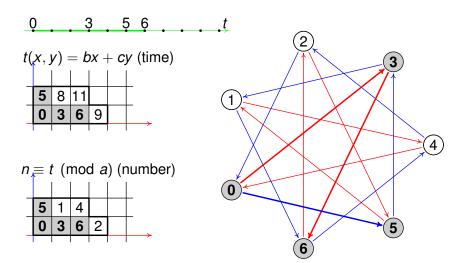

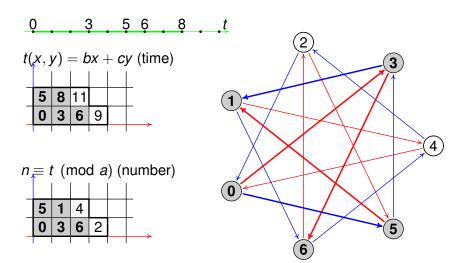

b = 3 (red step), c = 5 (blue step), a = 7 (number of vertices)

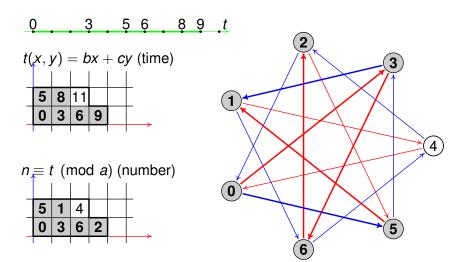

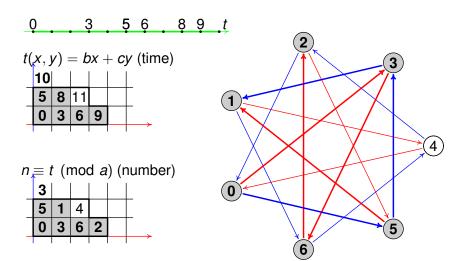

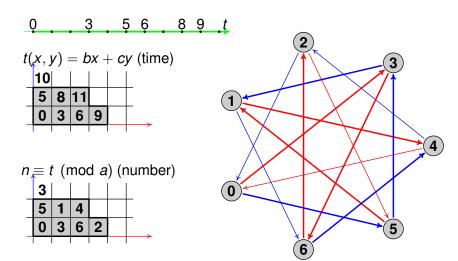

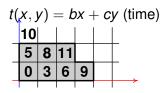

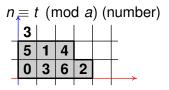

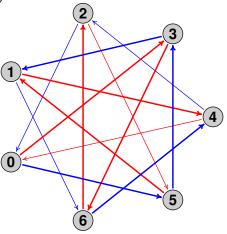

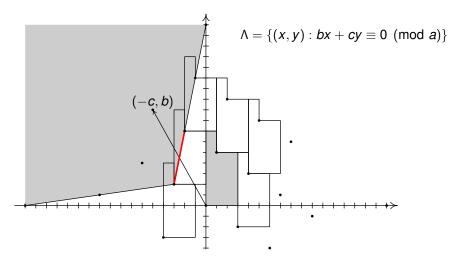

diam =
$$g(a, b, c) + a$$

< 🗐 🕨

From obvious property

$$0 = rac{s_{m+1}}{q_{m+1}} < rac{s_{m-1}}{q_{m-1}} < \ldots < rac{s_1}{q_1} < rac{s_0}{q_0} = \infty$$

follows that for some n

$$\frac{s_n}{q_n} \leq \frac{c}{b} < \frac{s_{n-1}}{q_{n-1}}.$$

From obvious property

$$0 = \frac{s_{m+1}}{q_{m+1}} < \frac{s_{m-1}}{q_{m-1}} < \ldots < \frac{s_1}{q_1} < \frac{s_0}{q_0} = \infty$$

follows that for some n

$$\frac{s_n}{q_n} \leq \frac{c}{b} < \frac{s_{n-1}}{q_{n-1}}.$$

Theorem (Ö. Rödseth, 1978)

$$f(a, b, c) = bs_{n-1} + cq_n - \min\{bs_n, cq_{n-1}\}.$$

Rödseth's formula

Rödseth's formula can be written in terms of reduced regular continued fraction. We want to find f(a, b, c) for (a, b) = (a, c) = (b, c) = 1. Let *I* is such that

$$bl \equiv c \pmod{a}, \quad 1 \leq l \leq a.$$

Reduced regular continued fraction

$$\frac{a}{l} = \langle a_1, \ldots, a_m \rangle = a_1 - \frac{1}{a_2 - \ldots - \frac{1}{a_m}},$$

where $a_1, \ldots, a_m \ge 2$, defines sequences $\{s_j\}, \{q_j\}$ by

$$\frac{q_{j+1}}{q_j} = \langle a_j, \ldots, a_1 \rangle, \qquad \frac{s_j}{s_{j+1}} = \langle a_{j+1}, \ldots, a_m \rangle \qquad (0 \le j \le m).$$

Rödseth's formula

Rödseth's formula can be written in terms of reduced regular continued fraction. We want to find f(a, b, c) for (a, b) = (a, c) = (b, c) = 1. Let *I* is such that

$$bl \equiv c \pmod{a}, \qquad 1 \leq l \leq a.$$

Reduced regular continued fraction

$$\frac{a}{l} = \langle a_1, \ldots, a_m \rangle = a_1 - \frac{1}{a_2 - \ldots - \frac{1}{a_m}},$$

where $a_1, \ldots, a_m \ge 2$, defines sequences $\{s_j\}, \{q_j\}$ by

$$\frac{q_{j+1}}{q_j} = \langle a_j, \ldots, a_1 \rangle, \qquad \frac{s_j}{s_{j+1}} = \langle a_{j+1}, \ldots, a_m \rangle \qquad (0 \le j \le m).$$

Rödseth's formula

Rödseth's formula can be written in terms of reduced regular continued fraction. We want to find f(a, b, c) for (a, b) = (a, c) = (b, c) = 1. Let *I* is such that

$$bl \equiv c \pmod{a}, \qquad 1 \leq l \leq a.$$

Reduced regular continued fraction

$$\frac{a}{l} = \langle a_1, \ldots, a_m \rangle = a_1 - \frac{1}{a_2 - \ldots - \frac{1}{a_m}},$$

where $a_1, \ldots, a_m \ge 2$, defines sequences $\{s_j\}, \{q_j\}$ by

$$\frac{q_{j+1}}{q_j} = \langle a_j, \ldots, a_1 \rangle, \qquad \frac{s_j}{s_{j+1}} = \langle a_{j+1}, \ldots, a_m \rangle \qquad (0 \le j \le m).$$

We have one-to-one correspondence between the set of quadruples $(q_n, s_n, q_{n-1}, s_{n-1})$ (taken for all lattices Λ_l) and the solutions of the equation

 $x_1y_1 - x_2y_2 = a$

with $0 \le x_2 < x_1$, $0 \le y_2 < y_1$, $(x_1, x_2) = (y_1, y_2) = 1$:

 $(q_n, s_n, q_{n-1}, s_{n-1}) \longleftrightarrow (x_1, x_2, y_2, y_1).$

A (10) A (10)

From the equation

$$x_1y_1 - x_2y_2 = a$$

it follows that

$$x_1y_1 \equiv a \pmod{x_2},$$

and Kloosterman sums

$$\mathcal{K}_{q}(l,m,n) = \sum_{\substack{x,y=1\\xy\equiv l \pmod{q}}}^{q} e^{2\pi i \frac{mx+ny}{q}}$$

come into play. Solutions of the congruence $xy \equiv l \pmod{q}$ are uniformly distributed due to the bounds for Kloosterman sums.

This fact allows to calculate sums of the form

$$\sum_{xy\equiv l \pmod{q}} F(x,y)$$

and

$$\sum_{x_1y_1-x_2y_2=a}F(x_1,y_1,x_2,y_2).$$

In particular it allows to study distribution of Frobenius numbers f(a, b, c).

4 A N

∃ >

Rödseth (1990) proved a lower bound for Frobenius numbers:

$$f(a_1,\ldots,a_n) \geq \sqrt[n-1]{(n-1)!a_1\ldots a_n}.$$

Conjecture (Davison, 1994) Average value of normalized Frobenius numbers $\frac{f(a,b,c)}{\sqrt{abc}}$ over cube $[1, N]^3$ tends to some constant as $N \to \infty$.

Rödseth (1990) proved a lower bound for Frobenius numbers:

$$f(a_1,\ldots,a_n) \geq \sqrt[n-1]{(n-1)!a_1\ldots a_n}.$$

Conjecture (Davison, 1994)

Average value of normalized Frobenius numbers $\frac{f(a,b,c)}{\sqrt{abc}}$ over cube $[1, N]^3$ tends to some constant as $N \to \infty$.

Conjecture (Arnold, 1999, 2005)

There is weak asymptotic for Frobenius numbers: for arbitrary *n* average value of $f(x_1, \ldots, x_n)$ over small cube with a center in (a_1, \ldots, a_n) approximately equal to $c_n \sqrt[n-1]{a_1 \ldots a_n}}$ for some constant $c_n > 0$.

Theorem (Bourgain and Sinaĭ, 2007)

Normalized Frobenius numbers $\frac{f(a,b,c)}{\sqrt{abc}}$ (under some natural assumption) have limiting density function.

Weak asymptotic

Let $x_1, x_2 > 0$ and $M_a(x_1, x_2) = \{(b, c) : 1 \le b \le x_1 a, 1 \le c \le x_2 a, (a, b, c) = 1\}.$

3

Let $x_1, x_2 > 0$ and $M_a(x_1, x_2) = \{(b, c) : 1 \le b \le x_1 a, 1 \le c \le x_2 a, (a, b, c) = 1\}.$

Theorem (A.U., 2009)

Frobenius numbers f(a, b, c) have weak asymptotic $\frac{8}{\pi}\sqrt{abc}$:

$$\frac{1}{a^{3/2}|M_a(x_1,x_2)|}\sum_{(b,c)\in M_a(x_1,x_2)}\left(f(a,b,c)-\frac{8}{\pi}\sqrt{abc}\right)=O_{\varepsilon,x_1,x_2}(a^{-1/6+\varepsilon}).$$

Davison's conjecture holds in a stronger form:

$$\frac{1}{|M_a(x_1,x_2)|} \sum_{(b,c)\in M_a(x_1,x_2)} \frac{f(a,b,c)}{\sqrt{abc}} = \frac{8}{\pi} + O_{\varepsilon,x_1,x_2}(a^{-1/6+\varepsilon}).$$

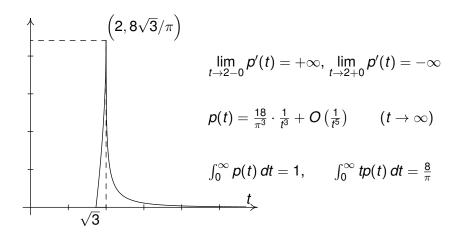

Theorem (A.U., 2010)

Normalized Frobenius numbers of three arguments have limiting density function:

$$\frac{1}{|M_a(x_1, x_2)|} \sum_{\substack{(b,c) \in M_a(x_1, x_2) \\ f(a,b,c) \leq \tau \sqrt{abc}}} 1 = \int_0^\tau \rho(t) \, dt + O_{\varepsilon, x_1, x_2, \tau}(a^{-1/6 + \varepsilon}),$$

where

$$p(t) = \begin{cases} 0, & \text{if } t \in [0, \sqrt{3}]; \\ \frac{12}{\pi} \left(\frac{t}{\sqrt{3}} - \sqrt{4 - t^2} \right), & \text{if } t \in [\sqrt{3}, 2]; \\ \frac{12}{\pi^2} \left(t \sqrt{3} \arccos \frac{t + 3\sqrt{t^2 - 4}}{4\sqrt{t^2 - 3}} + \frac{3}{2}\sqrt{t^2 - 4} \log \frac{t^2 - 4}{t^2 - 3} \right), & \text{if } t \in [2, +\infty). \end{cases}$$

3

Triples (α, β, r), where

$$\alpha = rac{q_n}{\sqrt{a/\xi}}, \quad \beta = rac{s_{n-1}}{\sqrt{a\xi}}, \quad r = rac{s_n}{\sqrt{a\xi}} \qquad (\xi = c/b)$$

(normalized edges of L-shaped diagram) have joint limiting density function

$$p(\alpha, \beta, r) = \begin{cases} \frac{2}{\zeta(2)r}, & r \le \min\{\alpha, \beta\}, 1 \le \alpha\beta \le 1 + r^2, \\ 0 & \textit{else.} \end{cases}$$

It allows to study shortest cycles, average distances and another characteristics of L-shaped diagrams (double loop networks).

Weak asymptotic for genus

Let

$$n(a,b,c) = \#(\mathbb{N} \setminus \langle a,b,c \rangle)$$

be a genus of numerical semigroup $\langle a, b, c \rangle$ and let N(a, b, c) let be modified genus:

$$N(a, b, c) = n(a, b, c) + \frac{a}{2} + \frac{b}{2} + \frac{c}{2} - \frac{1}{2}.$$

It is more convenient because for $d \mid a, d \mid b$ we have

$$N(a,b,c) = d \cdot N\left(rac{a}{d},rac{b}{d},c
ight).$$

Theorem (Vorob'ev, 2016)

$$N(a,b,c) pprox rac{64}{5\pi^2} \sqrt{abc}.$$

Alexey Ustinov (Khabarovsk)

Kloosterman sums

For usual Kloosterman sums

$$\mathcal{K}_q(1,m,n) = \sum_{\substack{x,y=1\\xy\equiv 1 \pmod{q}}}^{q} e^{2\pi i \frac{mx+ny}{q}}$$

Estermann bound is known

$$|K_q(1, m, n)| \le \sigma_0(q) \cdot (m, n, q)^{1/2} \cdot q^{1/2}.$$

This bound can be generalized for the case of sums $K_q(I, m, n)$.

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

For usual Kloosterman sums

$$\mathcal{K}_q(1,m,n) = \sum_{\substack{x,y=1\xy\equiv 1\ (ext{mod }q)}}^q e^{2\pi i rac{mx+ny}{q}}$$

Estermann bound is known

$$|K_q(1, m, n)| \le \sigma_0(q) \cdot (m, n, q)^{1/2} \cdot q^{1/2}.$$

This bound can be generalized for the case of sums $K_q(I, m, n)$.

Theorem (A.U., 2008)

$$|\mathcal{K}_q(I,m,n)| \leq \sigma_0(q) \cdot \sigma_0((I,m,n,q)) \cdot (Im,In,mn,q)^{1/2} \cdot q^{1/2}$$

This estimate allows to count solutions of the congruence $xy \equiv l \pmod{a}$ in different regions.

Alexey Ustinov (Khabarovsk)

Kloosterman sums

Corollary

Let $q \ge 1$, $0 \le P_1$, $P_2 \le q$. Then for any real Q_1 , Q_2

$$\sum_{\substack{Q_1 < x \le Q_1 + P_1 \\ Q_2 < y \le Q_2 + P_2}} \delta_q(xy - 1) = \frac{\varphi(q)}{q^2} \cdot P_1 P_2 + O\left(\sigma_0(q) \log^2(q + 1)q^{1/2}\right)$$

and

$$\sum_{\substack{Q_1 < x \le Q_1 + P_1 \\ Q_2 < y \le Q_2 + P_2}} \delta_q(xy - l) = \frac{K_q(0, 0, l)}{q^2} \cdot P_1 P_2 + O\left(q^{1/2 + \varepsilon} + (q, l)q^{\varepsilon}\right).$$

- Distribution of diameters and distribution of shortest cycles in *circulant graphs* (often also called multi-loop networks) were studied by J. Marklof and A. Strömbergsson(2011). They proved existence of these distributions for arbitrary *n* and made some interesting numerical computations.
- For n = 3 Davison's conjecture in a stronger form was proved by D. Frolenkov (2011).
- Aliev, Henk, Hinrichs (2011) and Strömbergsson(2012) studied the properties of limiting distribution for normalized Frobenius numbers of arbitrary number of arguments.

Let $1 \le l \le a$, (l, a) = 1 and e_1 be the shortest vector of the lattice $\Lambda_l = \{(x, y) : lx \equiv y \pmod{a}\}.$

< 回 > < 三 > < 三 >

Let $1 \le l \le a$, (l, a) = 1 and e_1 be the shortest vector of the lattice $\Lambda_l = \{(x, y) : lx \equiv y \pmod{a}\}$. Basis (e_1, e_2) is reduced iff $e_2 \in \Omega(e_1)$ where $\Omega(e_1)$ is the plane region defined by inequalities

 $\|e_2\| \ge \|e_1\|$ and $\|e_2 \pm e_1\| \ge \|e_2\|$.

Let $1 \le l \le a$, (l, a) = 1 and e_1 be the shortest vector of the lattice $\Lambda_l = \{(x, y) : lx \equiv y \pmod{a}\}$. Basis (e_1, e_2) is reduced iff $e_2 \in \Omega(e_1)$ where $\Omega(e_1)$ is the plane region defined by inequalities

$$\|e_2\| \ge \|e_1\|$$
 and $\|e_2 \pm e_1\| \ge \|e_2\|$.

Moreover vector e_2 must lie on the line $I(e_1)$ defined by equation $det(e_1, e_2) = a$.

Let $1 \le l \le a$, (l, a) = 1 and e_1 be the shortest vector of the lattice $\Lambda_l = \{(x, y) : lx \equiv y \pmod{a}\}$. Basis (e_1, e_2) is reduced iff $e_2 \in \Omega(e_1)$ where $\Omega(e_1)$ is the plane region defined by inequalities

$$\|e_2\| \ge \|e_1\|$$
 and $\|e_2 \pm e_1\| \ge \|e_2\|$.

Moreover vector e_2 must lie on the line $I(e_1)$ defined by equation $det(e_1, e_2) = a$. By averaging over I we can get that vectors e_2 distributed uniformly on $\Omega(e_1) \cap I(e_1)$ with weight $||e_2||^{-1}$. Suppose $e_1 = \sqrt{a}(\alpha, \beta), e_2 = \sqrt{a}(\gamma, \delta)$.

Reduced bases in two-dimensional lattices

By integrating over e_1 we can get density function for $t = ||e_2||/\sqrt{a}$:

Reduced bases in two-dimensional lattices

By integrating over e_1 we can get density function for $t = ||e_2||/\sqrt{a}$:

$$p(t) = \begin{cases} 0, & \text{if } t \in \left[0, 1/\sqrt{2}\right]; \\ \frac{4}{\zeta(2)} \left(2t - \frac{1}{t} + \left(\frac{1}{t} - t\right)\right) \log\left(\frac{1}{t^2} - 1\right)\right), & \text{if } t \in \left[1/\sqrt{2}, 1\right]; \\ \frac{4}{\zeta(2)} \left(\frac{1}{t} + \left(t - \frac{1}{t}\right)\right) \log\left(1 - \frac{1}{t^2}\right)\right), & \text{if } t \in [1, \infty]. \end{cases}$$
