

# Compact tripotents and the Stone-Weierstrass Theorem for $C^*$ -algebras and $JB^*$ -triples

Francisco J. Fernández-Polo and Antonio M. Peralta\*

## Abstract

We establish some generalizations of Urysohn lemma for the *hull-kernel structure* in the setting of  $JB^*$ -triples. These results are the natural extensions of those obtained by C. A. Akemann in the setting of  $C^*$ -algebras. We also develop some connections with the classical Stone-Weierstrass problem for  $C^*$ -algebras and  $JB^*$ -triples.

## 1 Introduction

Let  $K$  be a topological compact Hausdorff space and let  $C(K)$  denote the Banach space of all complex-valued continuous functions on  $K$ . The classical Urysohn lemma allows us to describe the open subsets of  $K$  in the following way: a subset  $A \subseteq K$  is open if and only if there is an increasing net  $(x_\alpha)$  in  $C(K)$  satisfying that  $0 \leq x_\alpha(t) \nearrow 1$ , for each  $t \in A$ , and  $0 = x_\alpha(t)$  for each  $t \in K \setminus A$ . Clearly, a subset  $C \subseteq K$  is closed (equivalently, compact) if and only if  $K \setminus C$  is open. We can see the characteristic functions  $\chi_A$  as projections in the bidual of  $C(K)$ .

In the more general setting of non-necessarily abelian  $C^*$ -algebras the notions of open and compact projections in the bidual of a  $C^*$ -algebra are mainly due to C. A. Akemann ([1, 3], see also [5, 33]). Let  $A$  be a  $C^*$ -algebra. A projection  $p$  in  $A^{**}$  is said to be *open* if  $p$  is the weak\*-limit of a increasing net of positive elements in  $A$ , equivalently,  $pA^{**}p \cap A$  is weak\*-dense in  $pA^{**}p$  (compare [33, Proposition 3.11.9]). We say that  $p$  is *closed* whenever  $1 - p$  is open. Finally, a projection  $p$  is said to be *compact* if, and only if,  $p$  is closed and there exists a positive element  $a \in A$  such that  $p \leq a \leq 1$ , equivalently,

there is a monotone decreasing net  $(a_\lambda)$  in  $A_+$  with  $p \leq a_\lambda \leq 1$ , converging strongly to  $p$  (see for example [1] or [11, Definition-Lemma 2.47]). If  $A$  is unital then every closed projection in  $A^{**}$  is compact. Akemann called this collection of open projections in  $A^{**}$  the *hull-kernel structure (HKS)* of  $A$ . In the HKS of a C\*-algebra, the following generalization of Urysohn lemma was obtained by Akemann in [2, Theorem I.1]:

**Theorem 1.1.** *Let  $A$  be a unital C\*-algebra and let  $p$  and  $q$  be two closed projections in  $A^{**}$  with  $pq = 0$ . Then there exists  $a$  in  $A$  with  $0 \leq a \leq 1$ ,  $ap = 0$  and  $aq = q$ .  $\square$*

The generalizations of Urysohn Lemma to the setting of non-commutative C\*-algebras are closely related with the general Stone-Weierstrass problem for non-commutative C\*-algebras. This tool has been intensively developed since 1969 by C. A. Akemann [1, 2, 3], L. G. Brown [11], C. A. Akemann, J. Anderson and G. Pedersen [4] and C. A. Akemann and G. Pedersen [5], among others.

C\*-algebras belong to the more general class of complex Banach spaces known as JB\*-triples (see definition below). In this setting the role of projections is played by those elements called tripotents. Moreover, in [20] and [22] the notions of open, compact and closed tripotents in the bidual of a JB\*-triple are introduced and developed. The aim of this paper is the study of the *hull-kernel structure* in a JB\*-triple. In section 2 we prove some generalizations of Urysohn lemma for this HKS. Theorem 2.4 assures that whenever  $e$  and  $f$  are two orthogonal tripotents in the bidual of a JB\*-triple  $E$ , with  $e$  compact and  $f$  minimal, then there exist two orthogonal norm-one elements  $a_1$  and  $a_2$  in  $E$  such that  $e \leq a_1$  and  $f \leq a_2$ . The second Urysohn lemma type result is Theorem 2.10, where we establish the following: Let  $E$  be a JB\*-triple,  $x$  a norm-one element in  $E$  and  $u$  a compact tripotent in  $E^{**}$  relative to  $E$  satisfying that  $u \leq r(x)$ . Then there exists a norm-one element  $y$  in the inner ideal of  $E$  generated by  $x$ , such that  $u \leq y \leq r(x)$ .

In the last section we find some connections between the generalizations of Urysohn lemma to the HKS of a C\*-algebras or a JB\*-triple with the Stone-Weierstrass problem. As main result (see Theorem 3.5) we prove that whenever  $B$  is a JB\*-subtriple of a JB\*-triple  $E$  such that for every couple of orthogonal tripotents  $u, v$  in  $E^{**}$  with  $v$  minimal and  $u$  minimal or zero, there exist orthogonal elements  $x, y$  in  $B$  such that  $\|y\| = 1$ ,  $\|x\| \in \{0, 1\}$  and  $u \leq x$  and  $v \leq y$  (when  $u = 0$ , then we mean  $x = 0$ ), then  $B$  separates the extreme points of the closed unit ball of  $E^*$  and zero. This result combined with those obtained by C. A. Akemann [2] and B. Sheppard [39], on

the Stone-Weierstrass theorem for  $C^*$ -algebras and  $JB^*$ -triples, respectively, allow us to establish some new versions of the Stone-Weierstrass theorem in the setting of  $C^*$ -algebras and  $JB^*$ -triples.

We recall (c.f. [31]) that a  $JB^*$ -triple is a complex Banach space  $E$  together with a continuous triple product  $\{.,.,.\} : E \times E \times E \rightarrow E$ , which is conjugate linear in the middle variable and symmetric bilinear in the outer variables satisfying that,

- (a)  $L(a, b)L(x, y) = L(x, y)L(a, b) + L(L(a, b)x, y) - L(x, L(b, a)y)$ , where  $L(a, b)$  is the operator on  $E$  given by  $L(a, b)x = \{a, b, x\}$ ;
- (b)  $L(a, a)$  is an hermitian operator with non-negative spectrum;
- (c)  $\|L(a, a)\| = \|a\|^2$ .

Every  $C^*$ -algebra is a  $JB^*$ -triple via the triple product given by

$$2\{x, y, z\} = xy^*z + zy^*x,$$

and every  $JB^*$ -algebra is a  $JB^*$ -triple under the triple product

$$\{x, y, z\} = (x \circ y^*) \circ z + (z \circ y^*) \circ x - (x \circ z) \circ y^*.$$

A  $JBW^*$ -triple is a  $JB^*$ -triple which is also a dual Banach space (with a unique predual [9]). The second dual of a  $JB^*$ -triple is a  $JBW^*$ -triple [17]. Elements  $a, b$  in a  $JB^*$ -triple,  $E$ , are *orthogonal* if  $L(a, b) = 0$ . With each tripotent  $u$  (i.e.  $u = \{u, u, u\}$ ) in  $E$  is associated the *Peirce decomposition*

$$E = E_2(u) \oplus E_1(u) \oplus E_0(u),$$

where for  $i = 0, 1, 2$ ,  $E_i(u)$  is the  $\frac{i}{2}$  eigenspace of  $L(u, u)$ . The Peirce rules are that  $\{E_i(u), E_j(u), E_k(u)\}$  is contained in  $E_{i-j+k}(u)$  if  $i-j+k \in \{0, 1, 2\}$  and is zero otherwise. In addition,

$$\{E_2(u), E_0(u), E\} = \{E_0(u), E_2(u), E\} = 0.$$

The corresponding *Peirce projections*,  $P_i(u) : E \rightarrow E_i(u)$ , ( $i = 0, 1, 2$ ) are contractive and satisfy

$$P_2(u) = D(2D - I), \quad P_1(u) = 4D(I - D), \quad \text{and} \quad P_0(u) = (I - D)(I - 2D),$$

where  $D$  is the operator  $L(u, u)$  and  $I$  is the identity map on  $E$  (compare [23]). A non-zero tripotent  $u \in E$  is called *minimal* if and only if  $E_2(u) = \mathbb{C}u$ .

Let  $e$  and  $x$  be two norm-one elements in a JB\*-triple,  $E$ , with  $e$  tripotent. We shall say that  $e \leq x$  (respectively,  $x \leq e$ ) whenever  $L(e, e)x = e$  (respectively,  $x$  is a positive element in the JB\*-algebra  $E_2(e)$ ).

The strong\*-topology in a JBW\*-triple was introduced by T. J. Barton and Y. Friedman in [8]. This strong\*-topology can be defined in the following way: Given a JBW\*-triple  $W$ , a norm-one element  $\varphi$  in  $W_*$  and a norm-one element  $z$  in  $W$  such that  $\varphi(z) = 1$ , it follows from [8, Proposition 1.2] that the assignment

$$(x, y) \mapsto \varphi \{x, y, z\}$$

defines a positive sesquilinear form on  $W$ . Moreover, for every norm-one element  $w$  in such satisfying  $\varphi(w) = 1$ , we have  $\varphi \{x, y, z\} = \varphi \{x, y, w\}$ , for all  $x, y \in W$ . The law  $x \mapsto \|x\|_\varphi := (\varphi \{x, x, z\})^{\frac{1}{2}}$ , defines a prehilbertian seminorm on  $W$ . The strong\*-topology (noted by  $S^*(W, W_*)$ ) is the topology on generated by the family  $\{\|\cdot\|_\varphi : \varphi \in W_*, \|\varphi\| = 1\}$ .

The strong\*-topology is compatible with the duality  $(W, W_*)$  (see [8, Theorem 3.2]). The strong\*-topology was further developed in [36, 34]. In particular, the triple product is jointly strong\*-continuous on bounded sets (see [36, 34]).

Let  $W$  be a JBW\*-triple and let  $a$  be a norm-one element in  $W$ . The sequence  $(a^{2n-1})$  defined by  $a^1 = a$ ,  $a^{2n+1} = \{a, a^{2n-1}, a\}$  ( $n \in \mathbb{N}$ ) converges in the strong\*-topology (and hence in the weak\*-topology) of  $W$  to a tripotent  $u(a)$  in  $W$  (compare [20, Lemma 3.3]). This tripotent will be called the *support tripotent* of  $a$ . There exists a smallest tripotent  $r(a) \in W$  satisfying that  $a$  is positive in the JBW\*-algebra  $W_2(r(a))$ , and  $u(a) \leq a^{2n-1} \leq a \leq r(a)$ . This tripotent  $r(a)$  will be called the *range tripotent* of  $a$ . (Beware that in [20],  $r(a)$  is called the support tripotent of  $a$ ).

In [20], C. M. Edwards and G. T. Rüttimann introduced the concepts of *open* and *compact* tripotents in the bidual of a JB\*-triple. In [22], the authors of the present paper studied the notions of open and compact tripotents in a JBW\*-triple with respect to a weak\*-dense subtriple. Concretely, given a JBW\*-triple  $W$  and a weak\*-dense JB\*-subtriple  $E$  of  $W$ , a tripotent  $u$  in  $W$  is said to be *compact- $G_\delta$  relative to  $E$*  if  $u$  is the support tripotent of a norm one element in  $E$ . The tripotent  $u$  is said to be *compact relative to  $E$*  if  $u = 0$  or there exist a decreasing net,  $(u_\lambda) \subseteq W$ , of compact- $G_\delta$  tripotents relative to  $E$  converging, in the strong\*-topology of  $W$ , to the element  $u$  (compare [20, §4]). A tripotent  $u$  in  $W$  is said to be *open relative to  $E$*  if  $E \cap W_2(u)$  is weak\*-dense in  $W_2(u)$ . When  $E$  is a JB\*-triple, the range (respectively, the support) tripotent of every norm-one element in  $E$

is always an open (respectively, compact) tripotent in  $E^{**}$  relative to  $E$ .

**Notation** Given a Banach space  $X$ , we denote by  $X_1$ ,  $S_X$ , and  $X^*$  the closed unit ball, the unit sphere, and the dual space of  $X$ , respectively. If  $K$  is any convex subset of  $X$ , then we write  $\partial_e(K)$  for the set of extreme points of  $K$ .

## 2 The non-commutative Urysohn lemma for JB\*-triples

This section is mainly devoted to obtain some Urysohn lemma type results for the HKS of a JB\*-triple. We begin by developing some new properties of compact tripotents in the bidual of a JB\*-triple.

**Proposition 2.1.** *Let  $W$  and  $V$  be JBW\*-triples,  $E$  a weak\*-dense JB\*-subtriple of  $W$  and  $T : W \rightarrow V$  a surjective weak\*-continuous triple homomorphism such that  $\|T(x)\| = \|x\|$ , for all  $x$  in  $E$ . Suppose that  $e$  is a tripotent in  $W$ , then  $T(e)$  is compact relative to  $T(E)$  in  $V$  whenever  $e$  is compact relative to  $E$ . Moreover, if  $T$  is a triple isomorphism, then  $e$  is compact relative to  $E$  in  $W$  if and only if  $T(e)$  is compact relative to  $T(E)$  in  $V$ .*

*Proof.* Suppose that  $e \in W$  is compact relative to  $E$ . If  $T(e) = 0$ , then there is nothing to prove. Suppose that  $T(e)$  is a non-zero tripotent in  $V$ . By definition, there exists a decreasing net  $(u_\lambda)_{\lambda \in \Lambda} \subset W$ , of compact- $G_\delta$  tripotents relative to  $E$  (i.e.,  $\forall \lambda$  there exists  $a_\lambda \in S_E$  such that  $u_\lambda = u(a_\lambda)$ ), converging to  $e$  in the strong\*-topology of  $W$ .

From the hypothesis we know that, for each  $\lambda \in \Lambda$ ,  $\|T(a_\lambda)\| = \|a_\lambda\| = 1$ . Since, for each  $\lambda$ ,  $u(T(a_\lambda))$  coincides with the limit, in the weak\*-topology of  $V$ , of the sequence  $(T(a_\lambda)^{2n-1}) = (T(a_\lambda^{2n-1}))$ , and  $T$  is weak\*-continuous, we have  $u(T(a_\lambda)) = T(u(a_\lambda))$ . The conditions  $(u_\lambda)$  decreasing and  $T$  triple homomorphism imply that  $u(T(a_\lambda)) = T(u(a_\lambda))$  is also a decreasing net in  $V$ . Since  $T$  is weak\*-continuous, we deduce, from [36, Corollary 3], that  $T$  is  $S^*(W, W_*) - S^*(V, V_*)$ -continuous. Therefore,  $u(T(a_\lambda)) = T(u(a_\lambda))$  tends to  $T(e)$  in the  $S^*(V, V_*)$ -topology. This shows that  $T(e)$  is compact relative to  $T(E)$  in  $V$ .  $\square$

**Remark 2.2.** Note that under the assumptions of the previous proposition there is a relationship between compact- $G_\delta$  tripotents in  $W$  (respectively, range tripotents in  $W$ ) relative to  $E$  and compact- $G_\delta$  tripotents in  $V$  (respectively, range tripotents in  $V$ ) relative to  $T(E)$ . Indeed, let  $x \in E$

be a norm-one element. The sequence  $x^{2n-1}$  (respectively,  $x^{\frac{1}{2n-1}}$ ) tends to  $u(x)$  (respectively,  $r(x)$ ) in the weak\*-topology of  $W$ . Since  $T$  is a weak\*-continuous triple homomorphism isometric on  $E$ , it follows that  $T(u(x)) = u(T(x))$  (respectively,  $T(r(x)) = r(T(x))$ ). Moreover, since every compact- $G_\delta$  (respectively, range) tripotent in  $V$  relative to  $T(E)$  is of the form  $u(T(x))$  (respectively,  $r(T(x))$ ) for a suitable norm-one element  $x \in E$ , it is clear that  $T$  maps the set of compact- $G_\delta$  (respectively, range) tripotents in  $W$  relative to  $E$  onto the set of compact- $G_\delta$  (respectively, range) tripotents in  $V$  relative to  $T(E)$ .

In [16, Theorem 3.4] it is proved that every minimal tripotent in the bidual of a JB\*-triple,  $E$ , is compact relative to  $E$ . The next corollary shows that this result remains true for every minimal tripotent in a JBW\*-triple  $W$  for any weak\*-dense JB\*-subtriple of  $W$ .

Let  $E$  be a JB\*-triple. A subtriple  $I$  of  $E$  is said to be an *ideal* of  $E$  if  $\{E, E, I\} + \{E, I, E\} \subseteq I$ . We shall say that  $I$  is an *inner ideal* of  $E$  whenever  $\{I, E, I\} \subseteq I$ .

If  $E$  and  $F$  are two JB\*-triples, a representation  $\pi : E \rightarrow F$  is any triple homomorphism from  $E$  to  $F$ . Let  $j : E \rightarrow E^{**}$  be the canonical inclusion of  $E$  into its bidual. Each weak\*-closed ideal  $I$  of  $E^{**}$  is an M-summand (see [27]). Therefore there exists a weak\*-continuous contractive projection  $\pi : E^{**} \rightarrow I$ . The representation  $E \rightarrow I$  given by  $x \mapsto \pi j(x)$  is called *the canonical representation* of  $E$  corresponding to  $I$ . Suppose that  $E$  is a weak\*-dense JB\*-subtriple of a JBW\*-triple  $W$  and let  $\lambda : E \rightarrow W$  be the natural inclusion. From [7, Proposition 6], there exists a weak\*-closed triple ideal  $M$  of  $E^{**}$  and a triple isomorphism  $\Psi : W \rightarrow M$  satisfying that  $\Psi\lambda$  is the canonical representation of  $E$  corresponding to  $M$ .

**Corollary 2.3.** *Let  $E$  be a weak\*-dense JB\*-subtriple of a JBW\*-triple  $W$ . Let  $M$  be the weak\*-closed triple ideal of  $E^{**}$  and let  $\Psi : W \rightarrow M$  the triple isomorphism described in the above paragraph, satisfying that  $\Psi\lambda$  is the canonical representation of  $E$  corresponding to  $M$ . Let  $e$  be a tripotent in  $W$ . Then  $e$  is compact relative to  $E$  in  $W$  whenever  $\Psi(e)$  is compact relative to  $E$  in  $E^{**}$ . In particular, every minimal tripotent in  $W$  is compact relative to  $E$ .*

*Proof.* Let  $\pi : E^{**} \rightarrow M$  denote the canonical projection of  $E^{**}$  onto  $M$ . Clearly,  $\pi$  is a surjective weak\*-continuous triple homomorphism and if  $i : E \rightarrow W$  and  $j : E \rightarrow E^{**}$  denote the canonical inclusions of  $E$  into  $W$  and  $E^{**}$ , respectively, we have  $\Psi \circ i = \pi \circ j$ .

Let  $e \in W$  be a tripotent in  $W$  such that  $\Psi(e)$  is compact relative to  $E$  in  $E^{**}$ . Proposition 2.1 applied to  $\pi : E^{**} \rightarrow M$ ,  $E^{**}$  and  $E$ , gives  $\Psi(e)$  compact relative to  $\pi(E)$  in  $M$ . Again, Proposition 2.1 assures that  $e$  is compact relative to  $E$  in  $W$ .

Finally, if  $e$  is minimal in  $W$ , that is,  $W_2(e) = \mathbb{C}e$ , it is not hard to see that  $M_2(\Psi(e)) = E_2^{**}(\Psi(e)) = \mathbb{C}\Psi(e)$ , and hence  $\Psi(e)$  is a minimal tripotent in  $E^{**}$ . Therefore, from [16, Theorem 3.4], it follows that  $\Psi(e)$  is compact relative to  $E$  in  $E^{**}$ , which implies that  $e$  is compact relative to  $E$  in  $W$ .  $\square$

Let  $x$  be a norm-one element in a JB\*-triple  $E$ . Throughout the paper,  $E_x$  will denote the norm-closed JB\*-subtriple of  $E$  generated by  $x$ . It is known that  $E_x$  is JB\*-triple isomorphic (and hence isometric) to  $C_0(\Omega)$  for some locally compact Hausdorff space  $\Omega$  contained in  $[0, 1]$ , such that  $\Omega \cup \{0\}$  is compact and  $C_0(\Omega)$  denotes the Banach space of all complex-valued continuous functions vanishing at 0. Moreover, if we denote by  $\Psi$  the triple isomorphism from  $E_x$  onto  $C_0(\Omega)$ , then  $\Psi(x)(t) = t$  ( $t \in \Omega$ ) (cf. [30, 4.8], [31, 1.15] and [23]).

The following result is a first generalization of Urysohn Lemma to the setting of JB\*-triples.

**Theorem 2.4.** *Let  $E$  be a weak\*-dense JB\*-subtriple of a JBW\*-triple  $W$ . Let  $u, v$  be two orthogonal tripotents in  $W$  with  $u$  compact relative to  $E$  and  $v$  minimal. Then there exist two orthogonal elements  $a_1$  and  $a_2$  in  $E$  such that  $\|a_2\| = 1$ ,  $\|a_1\| \in \{0, 1\}$ ,  $u \leq a_1$  and  $v \leq a_2$ .*

*Proof.* When  $u = 0$ , we take  $a_1 = 0$  and the existence of  $a_2$  follows from the last statement in Corollary 2.3 (see also [16]). We may therefore assume  $u \neq 0$ .

Since  $v$  is a minimal tripotent in  $W$ , from [23, Proposition 4] it follows that there exists  $\varphi \in \partial_e((W_*)_1)$  satisfying  $\varphi(v) = 1$ .

Corollary 2.3 implies  $v$  compact relative to  $E$ . Now, [22, Proposition 2.3] assures that  $v$  and  $u$  are closed tripotents relative to  $E$ , that is,  $W_0(u) \cap E$  and  $W_0(v) \cap E$  are subtriples of  $W$  which are weak\*-dense in  $W_0(u)$  and  $W_0(v)$ , respectively. From the orthogonality of  $u$  and  $v$  we have  $u \in W_0(v)$  and  $v \in W_0(u)$ .

Let us denote  $F = W_0(u) \cap E$ . Since [16, Theorem 2.8] remains true when  $E^{**}$  is replaced with any JBW\*-triple  $W$  such that  $E$  is weak\*-dense in  $W$ , then applying this result to  $F$  and  $W_0(u)$ , it follows that for every  $\varepsilon, \delta > 0$ , there exist  $y \in F$  and a tripotent  $e \in W_0(u)$  such that  $e \leq v$ ,  $P_i(e)(v - y) = 0$  for  $i = 1, 2$ ,  $\|y\| \leq (1 + \delta)\|(P_2(e) + P_1(e))(v)\|$  and  $|\varphi(v - e)| < \varepsilon$ . Since  $\varepsilon$  can

be chosen arbitrary small and  $v$  is a minimal tripotent in  $W_0(u)$ , we have  $e = v$ . The same arguments given in [16, Lemma 3.1] assure the existence of a norm-one element  $b_2 \in F$  such that  $v \leq b_2$ .

Let  $F_{b_2}$  denote the JB\*-subtriple of  $F$  generated by  $b_2$ . As we have commented above, there exists a locally compact Hausdorff space  $L \subseteq [0, 1]$  with  $L \cup \{0\}$  compact such that  $F_{b_2}$  is isometrically isomorphic to  $C_0(L)$  under some surjective isometry denoted by  $\psi$  and  $\psi(b_2)(t) = t$ , for any  $t \in L$ . Let  $a_2$  and  $\tilde{a}_2 \in F_{b_2}$  the norm-one elements given by the expressions

$$\psi(a_2)(t) := \begin{cases} 0, & \text{if } 0 \leq t \leq \frac{3}{4}; \\ \text{affine}, & \text{if } \frac{3}{4} \leq t \leq 1; \\ 1, & \text{if } t = 1. \end{cases}$$

$$\psi(\tilde{a}_2)(t) := \begin{cases} 0, & \text{if } 0 \leq t \leq \frac{1}{2}; \\ \text{affine}, & \text{if } \frac{1}{2} \leq t \leq \frac{3}{4}; \\ 1, & \text{if } t \geq \frac{3}{4}. \end{cases}$$

Clearly  $v \leq u(b_2) \leq u(a_2) \leq a_2 \leq r(a_2) \leq \tilde{a}_2$ .

Now, Theorem 2.6 in [22] assures the existence of a norm-one element  $x$  in  $E$  such that  $u \leq x$ . We define

$$c_1 = P_0(\tilde{a}_2)(x) := x - 2L(z, z)x + Q(z)^2(x) \in E,$$

where  $z$  is the element in  $F_{\tilde{a}_2} = E_{\tilde{a}_2}$  satisfying  $\{z, r(\tilde{a}_2), z\} = \tilde{a}_2$  (compare [22, §2]). From [22, Lemma 2.5], we have  $c_1 \in E \cap W_0(r(a_2))$ , which, in particular, implies that  $c_1$  and  $a_2$  are orthogonal. We claim that

$$L(u, u) c_1 = u.$$

Indeed, since  $x \geq u$ , then  $x = u + P_0(u)(x)$ . Moreover, since  $z \in F_{\tilde{a}_2} = E_{\tilde{a}_2} \subseteq W_0(u)$ , it follows, from Peirce rules, that

$$\begin{aligned} L(u, u)c_1 &= \{u, u, x - 2L(z, z)x + Q(z)^2(x)\} \\ &= \{u, u, u + P_0(u)(x) - 2L(z, z)(u + P_0(u)(x)) + Q(z)^2(u + P_0(u)(x))\} \\ &= \{u, u, u\} + \{u, u, P_0(u)(x) - 2L(z, z)(P_0(u)(x)) + Q(z)^2(P_0(u)(x))\} = u. \end{aligned}$$

Again, the same arguments given in [16, Lemma 3.1] imply the existence of a norm-one element  $a_1 \in E_{c_1}$  such that  $u \leq a_1$ .  $\square$

In the case of von Neumann algebras the above theorem generalizes Theorem II.19 in [1] from the setting of biduals of C\*-algebras to the more general setting of von Neumann algebras.

**Corollary 2.5.** *Let  $A$  be a weak\*-dense  $C^*$ -subalgebra of a von Neumann algebra  $W$ . Let  $p, q$  be two orthogonal projections in  $W$  with  $p$  compact relative to  $A$  and  $q$  minimal. Then there exist two orthogonal positive elements  $a_1$  and  $a_2$  in  $A$  such that  $\|a_2\| = 1$ ,  $\|a_1\| \in \{0, 1\}$ ,  $p \leq a_1$  and  $q \leq a_2$ .  $\square$*

In some particular triple representations the results stated in Proposition 2.1 and Remark 2.2 can be improved. This is the case of the canonical representation of a  $JB^*$ -triple into the atomic part of its bidual. We recall that, given a  $JB^*$ -triple  $E$ , then  $E^{**}$  decomposes into an orthogonal direct sum of two weak\*-closed triple ideals  $A$  and  $N$ , where  $A$  (called *the atomic part of  $E^{**}$* ) coincides with the weak\*-closure of the linear span of all minimal tripotents in  $E^{**}$ ,  $E^* = A_* \oplus^{\ell_1} N_*$  and the closed unit ball of  $N_*$  has no extreme points, which implies that  $\partial_e(E_1^*) = \partial_e(A_{*,1})$  (compare [23, Theorems 1 and 2]). If  $\pi$  denotes the natural weak\*-continuous projection of  $E^{**}$  onto  $A$  and  $i : E \rightarrow E^{**}$  is the canonical inclusion, then the mapping  $\pi \circ i : E \rightarrow A$  is an isometric triple embedding called the canonical embedding of  $E$  into the atomic part of its bidual (see [24, proof of Proposition 1]).

We recall some notation needed in what follows. Let  $X$  be a Banach space. For each pair of subsets  $G, F$  in the unit ball of  $X$  and  $X^*$ , respectively, let the subsets  $G'$  and  $F$ , be defined by

$$G' = \{f \in B_{X^*} : f(x) = 1, \forall x \in G\}$$

and

$$F = \{x \in B_X : f(x) = 1 \forall f \in F\},$$

respectively.

**Proposition 2.6.** *Let  $E$  be a  $JB^*$ -triple, let  $\pi$  denote the canonical projection of  $E^{**}$  onto its atomic part and let  $i : E \rightarrow E^{**}$  be the canonical embedding of  $E$  into its bidual. The following assertions hold*

- a) *Let  $u$  and  $v$  be two compact tripotents in  $E^{**}$  relative to  $E$ . Then  $u \leq v$  if and only if  $\pi(u) \leq \pi(v)$ .*
- b) *For each compact tripotent  $u$  in  $\pi(E^{**})$  relative to  $\pi(E)$  there exists a unique compact tripotent  $e$  in  $E^{**}$  relative to  $E$  such that  $\pi(e) = u$ .*

*Proof.* a) Let us denote  $A := \pi(E^{**})$ . If  $u \leq v$  in  $E^{**}$ , then  $\pi(u) \leq \pi(v)$ , since  $\pi$  is a triple homomorphism. Suppose now that  $\pi(u) \leq \pi(v)$ . From [18, Theorem 4.4], we have

$$\{\pi(u)\}_{A_*} \subseteq \{\pi(v)\}_{A_*} \tag{1}$$

By [20, Theorem 4.5] together with the comments preceding Corollary 3.5 in [16], every non-zero compact tripotent in  $E^{**}$  relative to  $E$  majorises a minimal tripotent of  $E^{**}$ . In particular, if  $e$  is a compact tripotent in  $E^{**}$  with  $\pi(e) = 0$ , then  $e = 0$ . We may therefore assume that  $\pi(u)$  and hence  $\pi(v)$  are not zero.

From [20, Theorem 4.2], it follows that the sets  $\{u\}_{E^*}$  and  $\{v\}_{E^*}$  are non-empty  $\sigma(E^*, E)$ -compact and convex subsets of  $E_1^*$ . By the Krein-Milman theorem we have

$$\{u\}_{E^*} = \overline{\text{co}}^{\sigma(E^*, E)} \left( \partial_e(\{u\}_{E^*}) \right) \quad (2)$$

$$\{v\}_{E^*} = \overline{\text{co}}^{\sigma(E^*, E)} \left( \partial_e(\{v\}_{E^*}) \right) \quad (3)$$

Since  $\partial_e(E_1^*) = \partial_e(A_{*,1})$ , we have

$$\begin{aligned} \{\pi(u)\}_{A_*} \cap \partial_e(A_{*,1}) &= \{\pi(u)\}_{E^*} \cap \partial_e(E_1^*) \\ &= \{u\}_{E^*} \cap \partial_e(E_1^*) = \partial_e(\{u\}_{E^*}). \end{aligned}$$

Similarly,

$$\{\pi(v)\}_{A_*} \cap \partial_e(A_{*,1}) = \partial_e(\{v\}_{E^*}).$$

Finally, we deduce, from (1), (2), (3) and the last two expressions, that

$$\{u\}_{E^*} \subseteq \{v\}_{E^*},$$

which shows that  $u \leq v$  (compare [18, Theorem 4.4]).

b) Let  $u$  be a non-zero compact tripotent in  $A = \pi(E^{**})$  relative to  $\pi(E)$ . Then there exists a decreasing net  $(u_\lambda)$  of compact- $G_\delta$  tripotents in  $A$  relative to  $\pi(E)$  converging in the strong\*-topology of  $A$  to  $u$ . By Remark 2.2, for each  $\lambda$ , there is a norm-one element  $x_\lambda \in E$  such that

$$u_\lambda = u(\pi(x_\lambda)) = \pi(u(x_\lambda)).$$

Since  $\pi(u(x_\lambda))$  is a decreasing net of compact- $G_\delta$  tripotents, then (a) implies that  $(u(x_\lambda))$  is a decreasing net in  $E^{**}$ . By [20, Theorem 4.5] there exist a non-zero compact tripotent  $e \in E^{**}$  relative to  $E$  such that  $e$  coincides with the infimum of the family  $(u(x_\lambda))$ . Since  $\pi$  is weak\*-continuous and  $(u(x_\lambda))$  tends to  $e$  in the weak\*-topology of  $E^{**}$ , we have that  $\pi((u(x_\lambda))) \rightarrow \pi(e)$  in the  $\sigma(E^{**}, E^*)$ -topology, and hence  $\pi(e) = u$ . Finally, the uniqueness of  $e$  follows from (a).  $\square$

The above result is a partial generalization of Theorem II.17 in [1]. In the more particular setting of JB\*-algebras we have:

**Corollary 2.7.** *Let  $A$  be a JB\*-algebra, let  $\pi$  denote the canonical projection of  $A^{**}$  onto its atomic part and let  $i : A \rightarrow A^{**}$  be the canonical embedding of  $A$  into its bidual. The following assertions hold*

- a) *Let  $p$  and  $q$  be two compact projections in  $A^{**}$  relative to  $A$ . Then  $p \leq q$  if and only if  $\pi(p) \leq \pi(q)$ .*
- b) *For each compact projection  $p$  in  $\pi(A^{**})$  relative to  $\pi(A)$  there exists a unique compact projection  $q$  in  $A^{**}$  relative to  $A$  such that  $\pi(q) = p$ .  $\square$*

Given a JB\*-algebra  $A$ , the cone of all positive elements in  $A$  will be denoted by  $A_+$ , while  $A_+^*$  will denote the set of positive elements in  $A^*$ . Let  $W$  be a JBW\*-algebra. The symbol  $Q_*(W)$  will denote the set of all positive elements in  $W_*$  with norm less or equal to one.  $Q_*(W)$  will be called the *normal quasi-state space* of  $W$ . The *normal state space*,  $S_*(W)$ , is the set of all elements in  $Q_*(W)$  with norm equals to one. Given a projection  $p$  in  $W$  we shall denote  $F(p) = F_W(p) := \{\varphi \in Q_*(W) : \varphi(p) = \|\varphi\|\}$ . If  $A$  is a JB\*-algebra, then the set,  $Q(A)$  (respectively,  $S(A)$ ), of quasi-states (respectively, states) of  $A$  is defined as  $Q_*(A^{**})$  (respectively,  $S_*(A^{**})$ ).

The following result was proved by M. Neal in [32, Lemma 3.2 and Theorem 5.2].

**Proposition 2.8.** *Let  $A$  be a JB\*-algebra and let  $p$  be a projection in  $A^{**}$ . Then we have:*

- (a)  *$p$  is open relative to  $A$  if and only if there exists an increasing net  $(a_\lambda)$  in  $A_{1,+}$  with least upper bound  $p$ .*
- (b)  *$p$  is closed relative to  $A$  if and only if  $F(p)$  is  $\sigma(A^*, A)$ -closed in  $Q(A)$ .  $\square$*

The next result gives a characterization of compact projections in JB\*-algebra biduals. A similar result was obtained by C. A. Akemann, J. Anderson and G. K. Pedersen in the setting of C\*-algebra biduals (see [4, Lemma 2.4]).

Given a JB\*-algebra  $A$ ,  $\tilde{A} = A \oplus \mathbb{C}1$  will stand for the result of adjoining a unit to  $A$  (compare [26, §3.3]).  $\tilde{A}$  is also called the *unitization* of  $A$ .

**Proposition 2.9.** *Let  $A$  be a JB\*-algebra and let  $p$  be a projection in  $A^{**}$ . Then  $p$  is compact relative to  $A$  if and only if  $F(p) \cap S(A)$  is  $\sigma(A^*, A)$ -closed in  $Q(A)$ .*

*Proof.* The proof given in [4, Lemma 2.4] can be literally adapted to the present setting. We include here an sketch of the proof for completeness reasons. Suppose first that  $p$  is a non-zero compact projection in  $A^{**}$ . From [20, theorem 4.2] we have  $F(p) \cap S(A) = \{p\}$ , is  $\sigma(A^*, A)$ -closed in  $Q(A)$ .

Let  $\tilde{A}$  be the unitization of  $A$ . Each element  $\phi \in Q(\tilde{A})$  can be written in the form  $\phi = \psi + \alpha\phi_0$ , with  $\psi \in Q(A)$ ,  $\|\phi\| = \|\psi\| + |\alpha|$ , where  $\phi_0$  is the unique state of  $\tilde{A}$  satisfying  $\phi_0(A) = 0$  (compare [26, Lemma 3.6.6]). Since  $p \in A^{**}$  and hence  $\phi_0(p) = 0$ , we easily check that

$$F_{A^*}(p) \cap S(A) = F_{\tilde{A}^*}(p) \cap S(\tilde{A}).$$

Therefore,  $F_{A^*}(p) \cap S(A)$  is  $\sigma(A^*, A)$ -closed in  $Q(A)$  if and only if  $F_{\tilde{A}^*}(p) \cap S(\tilde{A})$  is  $\sigma(\tilde{A}^*, \tilde{A})$ -closed in  $Q(\tilde{A})$ . By Proposition 2.8, it follows that  $p$  is closed in  $(\tilde{A})^{**}$  and in  $A^{**}$ . Since, clearly  $p \leq 1_{\tilde{A}}$ , we deduce from [22, Theorem 2.6] that  $p$  is compact in  $(\tilde{A})^{**}$  relative to  $\tilde{A}$ . Let  $p_0$  be the minimal projection in  $(\tilde{A})^{**}$  satisfying  $\phi_0(p_0) = 1$ . Theorem 2.4 implies the existence of a norm-one element  $x \in \tilde{A}$  such that  $p_0$  and  $x$  are orthogonal and  $L(p, p)x = x \circ p = p$ . In particular  $x \in A$ , which gives  $p$  compact in  $A^{**}$  relative to  $A$  (compare [22, Theorem 2.6]).  $\square$

Let  $B$  be a  $JB^*$ -subtriple of a  $JB^*$ -triple  $E$ . Throughout the paper, we shall identify the weak\*-closure of  $B$  in  $E^{**}$  with  $B^{**}$ . Let  $x$  be a norm-one element and let  $E(x)$  denote the norm closure of  $\{x, E, x\}$  in  $E$ . It was proved by L. J. Bunce, Ch.-H. Chu and B. Zalar in [14, 15], that  $E(x)$  coincides with the norm-closed inner ideal of  $E$  generated by  $x$ ,  $E(x)$  is a  $JB^*$ -subalgebra of the  $JBW^*$ -algebra  $E(x)^{**} = E_2^{**}(r(x))$ , where  $r(x)$  is the range tripotent of  $x$  in  $E^{**}$ . Moreover,  $x \in E(x)_+$ .

We can now state the following version of Urysohn lemma which is a partial generalization of the result obtained by C. A. Akemann, J. Anderson and G. K. Pedersen in [4, Lemma 2.5] (see also [3, Lemma III.1], [11, Corollary 2.48], [5, Lemma 2.7]).

**Theorem 2.10.** *Let  $E$  be a  $JB^*$ -triple,  $x$  a norm-one element in  $E$  and  $u$  a compact tripotent in  $E^{**}$  relative to  $E$  satisfying that  $u \leq r(x)$ . Then there exists a norm-one element  $y$  in  $E(x)$  such that  $u \leq y \leq r(x)$ . Moreover,  $u$  is a compact tripotent in  $E_2^{**}(r(x)) = (E(x))^{**}$  relative to  $E(x)$ .*

*Proof.* We may assume that  $0 \neq u \leq r(x)$ . From [20, Theorem 4.2], there exists a set of norm-one elements  $\{a_\lambda\} \subset E$  satisfying that

$$\{u\}_{E^*} = \bigcap_{\lambda \in \Lambda} \{u(a_\lambda)\}, = \bigcap_{\lambda \in \Lambda} \{a_\lambda\}'. \quad (4)$$

Since  $u \leq r(x)$ , then  $u$  is a projection in  $E(x)^{**} = E_2^{**}(r(x))$ .

Since  $E(x)$  is a norm-closed inner ideal of  $E$ , it follows from [19, Theorem 2.6] every element  $\varphi \in E(x)^*$  has a unique norm-preserving linear extension to  $E$ . The restriction mapping  $\Psi : E_1^* \rightarrow E(x)_1^*$ ,  $\phi \mapsto \phi|_{E(x)}$ , is  $\sigma(E^*, E) - \sigma(E(x)^*, E(x))$ -continuous. Let  $\phi \in \{u\}_{E^*}$ . Since  $u$  is a projection in  $E_2^{**}(r(x))$  and  $\phi(u) = 1 = \|\phi|_{E_2^{**}(r(x))}\|$  we deduce that  $\phi|_{E_2^{**}(r(x))}$  belongs to  $S_*(E_2^{**}(r(x))) = S(E(x))$ , and hence  $\|\phi|_{E(x)}\| = 1$ . Again, the unique extension property (see [19, Theorem 2.6]) assures that

$$F_{E(x)^*}(u) \cap S(E(x)) = \{u\}_{E(x)^*} = \Psi \left( \{u\}_{E^*} \right).$$

If we show that  $F_{E(x)^*}(u) \cap S(E(x))$  is  $\sigma(E(x)^*, E(x))$ -closed in  $Q(E(x))$ , the thesis of the theorem will follow from Proposition 2.9. To see this, let  $(\varphi_\mu)$  be a net in  $F_{E(x)^*}(u) \cap S(E(x))$  converging to some  $\varphi$  in  $F_{E(x)^*}(u) \cap S(E(x))$  in the  $\sigma(E(x)^*, E(x))$ -topology. Since  $\Psi$  is surjective, there exist a net  $(\phi_\mu)$  in  $\{u\}_{E^*}$  and  $\phi \in E_1^*$  such that  $\Psi(\phi_\mu) = \varphi_\mu$  and  $\Psi(\phi) = \varphi$ . Since  $E_1^*$  is  $\sigma(E^*, E)$ -compact, there exists a subnet  $(\phi_\delta)$  converging to some  $\phi'$  in the  $\sigma(E^*, E)$ -topology. For each  $\lambda \in \Lambda$  we have  $\phi_\delta(a_\lambda) \rightarrow \phi'(a_\lambda)$ . In particular, since  $(\phi_\delta) \subset \{u\}_{E^*}$ , we have, by (4),  $\phi_\delta(a_\lambda) = 1$  for all  $\delta, \lambda$ , which implies  $\phi' \in \{u\}_{E^*}$ . Finally,  $\Psi(\phi_\delta) = \varphi_\delta$  tends to  $\Psi(\phi')$  in the  $\sigma(E(x)^*, E(x))$ -topology, thus

$$\varphi = \Psi(\phi) = \Psi(\phi') \in \Psi \left( \{u\}_{E^*} \right) = F_{E(x)^*}(u) \cap S(E(x)),$$

which finishes the proof.  $\square$

Theorem 2.10 allows us to get the following generalization of [1, Theorem II.17] and [3].

**Proposition 2.11.** *Let  $E$  be a  $JB^*$ -triple, let  $\pi$  denote the canonical projection of  $E^{**}$  onto its atomic part and let  $i : E \rightarrow E^{**}$  be the canonical embedding of  $E$  into its bidual. Then, for each range tripotent  $e$  in  $\pi(E^{**})$  relative to  $\pi(E)$  there exists a unique range tripotent  $r$  in  $E^{**}$  relative to  $E$  such that  $\pi(r) = e$ .*

*Proof.* Remark 2.2 assures the existence of such a tripotent, so the proof ends by proving the uniqueness. Suppose that there exist norm-one elements  $x, y \in E$  such that  $\pi(r(x)) = \pi(r(y)) = e$ . By [31], there exist a locally compact Hausdorff space  $L \subseteq [0, 1]$  with  $L \cup \{0\}$  compact such

that  $E_x$  is isometrically isomorphic to  $C_0(L)$ . Let us define  $u_n = \chi_{L \cap [1/n, 1]}$ ,  $n \in \mathbb{N}$ . Clearly,  $u_n$  is a compact tripotent in  $E^{**}$  relative to  $E$  and  $u_n$  is an increasing sequence converging to  $r(x)$  in the weak\*-topology of  $E^{**}$ .  $\pi(u_n) \leq \pi(r(x)) = e = \pi(r(y))$  and by Proposition 2.6 and Theorem 2.10 there is a sequence of norm-one elements  $(z_n) \subset E(y)$  satisfying that  $\pi(u_n) \leq \pi(z_n) \leq \pi(r(y))$ . Again, Proposition 2.6 gives  $u_n \leq z_n \leq r(y)$ . Finally, since  $E_2^{**}(r(y))$  is weak\*-closed and  $(u_n)$  tends to  $r(x)$  in the weak\*-topology we have  $r(x) \leq r(y)$ . Symmetrically, we get  $r(y) \leq r(x)$ .  $\square$

**Remark 2.12.** Let  $x$  and  $y$  be two norm-one elements in a JB\*-triple  $E$ . Suppose that  $\pi$  is the projection of  $E^{**}$  onto its atomic part. In the proof of the above proposition we showed that  $r(x) \leq r(y)$  if, and only if,  $\pi(r(x)) \leq \pi(r(y))$ . This result remains true for open tripotents, the proof follows from a recent paper by A. Steptoe (We are indebted to L. J. Bunce for telling us about Steptoe's results). Theorem 8.3 in [40] assures that whenever  $J$  and  $I$  are two norm-closed inner ideals of  $E$ , then  $I \subseteq J$  if, and only if,  $\partial_e(I^*_1) \subseteq \partial_e(J^*_1)$ , which is equivalent to  $\pi(I^{**}) \subseteq \pi(J^{**})$ . Suppose that  $e$  and  $f$  are two open tripotents in  $E^{**}$  relative to  $E$  with  $\pi(e) \leq \pi(f)$ . Since  $E \cap E_2^{**}(e)$  and  $E \cap E_2^{**}(f)$  are two norm-closed inner ideals of  $E$  and  $\pi(e) \leq \pi(f)$ , we have  $\pi(E \cap E_2^{**}(e)) \subseteq \pi(E \cap E_2^{**}(f))$ . Thus, by [40, Theorem 8.3], we have  $E \cap E_2^{**}(e) \subseteq E \cap E_2^{**}(f)$ , and hence  $e \leq f$ . Since  $\pi(e) \leq \pi(f)$  always follows from  $e \leq f$ , we therefore have  $e \leq f$ , if and only if,  $\pi(e) \leq \pi(f)$ , for every couple of open tripotents  $e, f$  in  $E^{**}$  relative to  $E$ .

In the setting of C\*-algebras, C. A. Akemann, J. Anderson and G. Pedersen proved, in [4, Proposition 2.6], the following stronger version of the Urysohn Lemma. Let  $A$  be a C\*-algebra and let  $p$  and  $q$  be two closed orthogonal projections in  $A^{**}$  with  $p$  compact and  $\|ap\| < \varepsilon$  for some  $a$  in  $A$ . Then there are orthogonal open projections  $r, s \in A^{**}$  such that  $p \leq r$ ,  $q \leq s$  and  $\|ar\| < \varepsilon$ . We do not know if we can obtain a similar result in the setting of JB\*-triples.

**Problem 2.13.** Let  $E$  be a JB\*-triple and let  $e, f$  be two non-zero orthogonal compact tripotents in  $E^{**}$  relative to  $E$ . Do there exist orthogonal norm-one elements  $x, y$  in  $E$  such that  $e \leq x$  and  $f \leq y$ ?

**Problem 2.14.** Can we replace in Theorem 2.10 the range tripotent,  $r(x)$ , with any open tripotent in  $E^{**}$  relative to  $E$ ?

### 3 Connections with the Stone-Weierstrass Theorem for C\*-algebras and JB\*-triples

As we have commented in the introduction, the generalizations of Urysohn Lemma to the setting of non-commutative C\*-algebras are closely related with the general Stone-Weierstrass problem for non-commutative C\*-algebras. This tool has been intensively developed and applied to the Stone-Weierstrass problem in papers like [1, 2, 3, 4, 5] and [11].

The Stone-Weierstrass problem for C\*-algebras can be concretely stated as follows:

Let  $B$  be a C\*-subalgebra of a C\*-algebra  $A$ . Suppose that  $B$  separates the pure states of  $A$  and zero. Is  $B$  equal to  $A$ ?

I. Kaplansky gave a positive answer to the above problem for the special class of Type I C\*-algebras in [29]. For general C\*-algebras, many authors gave partial answer to the Stone-Weierstrass problem by including various additional conditions (see for example [29, 28, 25, 1, 2, 37, 21, 12, 6] and [10] among others).

We are particularly interested in the following Stone-Weierstrass type Theorem proved by C. A. Akemann in [2, Theorem II.7].

**Theorem 3.1.** *Let  $B$  be a C\*-subalgebra of a unital C\*-algebra  $A$  such that  $B$  separates the pure states of  $A$  and zero. Suppose that for every pair of orthogonal projections  $p, q$  in  $A^{**}$  with  $q$  minimal and  $p$  compact relative to  $A$ , there exists orthogonal (positive) elements  $x, y$  in  $B$  such that  $\|y\| = 1$ ,  $\|x\| \in \{0, 1\}$ ,  $p \leq x$  and  $q \leq y$ . Then  $B = E$ .  $\square$*

In the statement of [2, Theorem II.7] it is not explicitly included in the hypothesis that  $B$  separates the pure states of  $A$  and zero. However, the proof uses the results in [1, §3], where this condition is assumed (see [1, page 285] and [2, page 305]).

In the setting of JB-algebras and JB\*-triples an intensive study of the Stone-Weierstrass problem was developed by B. Sheppard [38, 39]. Among others results, B. Sheppard generalizes the result obtained by Kaplansky for postliminal JB\*-algebras and JB\*-triples in the following result.

**Theorem 3.2.** *[39, Theorem 5.7] Let  $B$  be a JB\*-subtriple of a JB\*-triple  $E$  such that  $B$  separates the extreme points of the closed unit ball of  $E^*$ . Then, if  $E$  or  $B$  is postliminal,  $E = B$ .  $\square$*

The aim of this section is an analysis of the connections between the Stone-Weierstrass theorem and the Urysohn lemma type results for JB\*-triples, analogous to that made by C. A. Akemann in the setting of C\*-algebras.

The following definition is inspired on Urysohn Lemma for JB\*-triples proved in Theorem 2.4. We introduce this property just to simplify the notation in this paper.

**Definition 3.3.** *Let  $B$  be a JB\*-subtriple of a JB\*-triple  $E$ . We say that  $B$  satisfies the SW-property with respect to  $E$  if and only if for every couple of orthogonal tripotents  $u, v$  in  $E^{**}$  with  $v$  minimal and  $u$  compact relative to  $E$ , there exist orthogonal elements  $x, y \in B$  such that  $\|y\| = 1$ ,  $\|x\| \in \{0, 1\}$ ,  $u \leq x$  and  $v \leq y$ . When  $u = 0$ , then we mean  $x = 0$  in  $u \leq x$ .*

Theorem 2.4 shows that every JB\*-triple has the SW-property with respect to itself.

**Lemma 3.4.** *Let  $A$  be a JBW\*-algebra and let  $p, q$  be minimal projections in  $A$ . Suppose that  $q = q_2 + q_1 + q_0$  is the Peirce decomposition of  $q$  with respect to  $p$  and  $\varphi_q$  in  $\partial_e(A_{*,1})$  such that  $\varphi_q(q) = 1$ . Then, either  $p = q$  or  $\varphi_q(q_0) \neq 0$ .*

*Proof.* By [26, 2.4.16 and 2.4.21] we have

$$P_2(p) = U_p^2 \circ * = U_{p^2} \circ *,$$

$$P_0(p) = U_{1-p} \circ *,$$

where  $U_p(x) := \{p, x^*, p\}$  and  $*$  denotes the canonical involution of  $A$ . Suppose that  $\varphi_q(q_0) = 0$ . We claim that  $q = p$ . Indeed, by [23, Proposition 1] and the hypothesis we have

$$0 = \varphi_q(q_0) = \varphi_q(U_{1-p}(q)) = \varphi_q(U_q U_{1-p}(q)).$$

Since  $q$  is minimal and  $\varphi_q$  is faithful in  $A_2(q) = \mathbb{C}q$ , we have

$$U_q U_{1-p}(q) = 0.$$

Now by [26, 2.4.18] it follows that

$$U_q U_{1-p}(q) = U_q U_{1-p} U_q(q) = U_{\{q, 1-p, q\}}(q) = 0.$$

However, since  $1 - p \geq 0$ , by [26, 3.3.6], we have  $\{q, 1 - p, q\}$  is a positive element in  $A_2(q)$ . Moreover, since  $q$  is the unit element in  $A_2(q)$  and  $U_{\{q, 1-p, q\}}(q) = 0$ , it follows that  $\{q, 1 - p, q\} = q - P_2(q)p = 0$ . Finally, the equality  $p = q$  can be derived from the minimality of  $p$ , since  $q - P_2(q)p = 0$  and [23, Lemma 1.6] imply that  $p = q + P_0(q)p$ .  $\square$

Let  $E$  be a JB\*-triple. Throughout the paper  $\text{MinTri}(E)$  will stand for the set of all minimal tripotents in  $E$ .

**Theorem 3.5.** *Let  $B$  be a JB\*-subtriple of a JB\*-triple  $E$ . Suppose that for every  $u \neq v$  in  $\text{MinTri}(E) \cup \{0\}$ , with  $u$  and  $v$  orthogonal, there exist orthogonal elements  $x, y \in B$  such that  $\|y\|, \|x\| \in \{0, 1\}$  and  $u \leq x$  and  $v \leq y$  (if  $u = 0$  or  $v = 0$ , we mean  $x = 0$  or  $y = 0$ , respectively). Then  $B$  separates  $\partial_e(E_1^*) \cup \{0\}$ .*

*Proof.* Let  $\varphi_1 \neq \varphi_2$  in  $\partial_e(E_1^*) \cup \{0\}$ . If  $\varphi_1 = 0$ , then there is a minimal tripotent  $u_2$  in  $E^{**}$  such that  $\varphi_2(u_2) = 1$  (compare [23, Proposition 4]). Now, the hypothesis on  $B$  applied to 0 and  $u_2$ , assure the existence of orthogonal elements  $x, y \in B$  such that  $\|y\|, \|x\| \in \{0, 1\}$  and  $0 \leq x$  and  $u_2 \leq y$ . In particular  $0 = \varphi_1(y) \neq \varphi_2(y) = 1$ . We may therefore assume  $\varphi_1, \varphi_2 \neq 0$ .

Take  $u_1 \neq u_2$  minimal tripotents in  $E^{**}$ , such that  $\varphi_i(u_i) = 1$ , for  $i = 1, 2$ . As we have commented in the previous paragraph, the hypothesis imply the existence of a norm-one element  $a \in B$ , such that  $u_1 \leq a$  and hence  $\varphi_1(a) = 1$ . If  $\varphi_2(a) \neq 1$ , then  $B$  separates  $\varphi_1, \varphi_2$  and we finish. We may therefore assume that  $\varphi_2(a) = 1$ . In this case, by [23, Propositions 1, 2 and Lemma 1.6]  $u_2 \leq a$ . Therefore,  $u_1, u_2 \leq a \leq r(a)$ , which implies that  $u_1$  and  $u_2$  are minimal projections in the JBW\*-algebra  $E_2^{**}(r(a))$ . From Lemma 3.4 and the hypothesis, we have  $\varphi_2(P_0(u_1)(u_2)) \neq 0$ . Moreover, from [8, page 258], it follows that  $0 < |\varphi_2(P_0(u_1)(u_2))| \leq \|\varphi_2(P_0(u_1)(u_2))\|_{\varphi_2}$ .

Let  $A$  denote the atomic part of  $E^{**}$ . Clearly,  $P_0(u_1)(A) \subset A$  and hence  $P_0(u_1)(A)$  coincides with the weak\*-closure of the linear span of  $\text{MinTri}(E^{**}) \cap E_0^{**}(u_1)$  (compare [23]). Since  $0 < |\varphi_2(P_0(u_1)(u_2))|$  we have  $\varphi_2|_{P_0(u_1)(A)} \neq 0$ , and hence there exists a minimal tripotent  $w \in \text{MinTri}(E^{**}) \cap E_0^{**}(u_1)$ , such that  $0 < \varphi_2(w) \leq \|w\|_{\varphi_2}$ .

Finally, by hypothesis, there are two orthogonal norm-one elements  $x, y$  in  $B$  such that  $u_1 \leq x$  and  $w \leq y$ . In particular  $0 < \|w\|_{\varphi_2} \leq \|y\|_{\varphi_2}$  and  $\varphi_1(x) = 1$ . Therefore,

$$|\varphi_2(x)|^2 \leq \|x\|_{\varphi_2}^2 < \|x\|_{\varphi_2}^2 + \|y\|_{\varphi_2}^2 = \|x + y\|_{\varphi_2}^2 \leq \|x + y\|^2 = 1,$$

which proves the desired statements.  $\square$

Since every minimal tripotent in the bidual of a JB\*-triple is compact (see [16, Theorem 3.4]) we have:

**Corollary 3.6.** *Let  $B$  be a JB\*-subtriple of a JB\*-triple  $E$ . Suppose that  $B$  has the SW-property with respect to  $E$ . Then  $B$  separates  $\partial_e(E_1^*) \cup \{0\}$ .*

The significant results obtained by B. Sheppard on the Stone-Weierstrass theorem for JB\*-triples in [39] allow us to get the following result connecting the SW-property and the Stone-Weierstrass Theorem for postliminal JB\*-triples.

**Corollary 3.7.** *Let  $B$  a JB\*-subtriple of a JB\*-triple  $E$ . Suppose that  $B$  has the SW-property with respect to  $E$ , and  $E$  or  $B$  is postliminal. Then  $B = E$ .*

*Proof.* This follows from Theorems 3.5 and 3.2 (see [39, Theorem 5.7]).  $\square$

**Remark 3.8.** Let  $A$  be a C\*-algebra regarded as a JB\*-triple and let  $p$  be a projection in  $A^{**}$ . Let  $\circ$  denote the Jordan product on  $A$ . Suppose that  $x$  is a norm-one element in  $A$  such that  $L(p, p)x = p$  (that is,  $p \leq x$  in  $A^{**}$  regarded the latter as a JB\*-triple), and hence  $x = p + P_0(p)(x)$ . In this case  $L(p, p)(x \circ x^*) = p$ . This shows that  $p \leq x \circ x^*$ .

Now, the proof given in Theorem 3.5 can be literally adapted, via Remark 3.8, to show that the assumption of  $B$  separating the pure states of  $A$  and zero can be dropped in Theorem 3.1 (see also [2, Theorem II.7]).

**Corollary 3.9.** *Let  $B$  be a C\*-subalgebra of a C\*-algebra  $A$ . Suppose that for every pair of orthogonal projections  $p, q$  in  $A^{**}$  with  $q$  minimal and  $p$  compact relative to  $A$ , there exists orthogonal (positive) elements  $x, y$  in  $B$  such that  $\|y\| = 1$ ,  $\|x\| \in \{0, 1\}$ ,  $p \leq x$  and  $q \leq y$ . Then  $B = A$ .*

*Proof.* The proof of Theorem 3.5 can be literally followed up to its last part. To finish, in this case, we note that the element  $w$  can be chosen as a minimal projection, for example  $ww^*$  or  $w^*w$ .  $\square$

**Acknowledgments:** The authors would like to thank L. J. Bunce for fruitful comments and discussions during the preparation of this paper.
