We describe the construction of the Saccheri quadrilateral in the hyperbolic plane using the notion of translation according to a hyperbolic line. Also, we describe the construction of the Lambert quadrilateral using the notion of translation along a line, while establishing the necessary and sufficient condition for the existence and uniqueness of such a quadrilateral. We developed some computer software, in *Mathematica*, oriented to draw the hyperbolic isometries, so much on the Poincaré's half-plane and disk. This software package, named `hyperbol.m`, is available at the Internet address: <http://www.ugr.es/local/ruiz/software.htm>. With this software we have created the graphics which appear in this poster. Finally, the Lambert and Saccheri quadrilaterals that tile the hyperbolic plane, by using triangular Non-Euclidean Crystallographic Groups, are described. And explicit examples of these tessellations are given.
